## APPLICATION ELEMENTS

See MPEP chapter 600 concerning utility patent application contents

1.  \* Fee Transmittal Form (e.g., PTO/SB/17)  
(Submit an original and a duplicate for fee processing)
2.  Specification [Total Pages 20]  
(preferred arrangement set forth below)
  - Descriptive title of the Invention
  - Cross References to Related Applications
  - Statement Regarding Fed sponsored R & D
  - Reference to Microfiche Appendix
  - Background of the Invention
  - Brief Summary of the Invention
  - Brief Description of the Drawings (if filed)
  - Detailed Description
  - Claim(s)
  - Abstract of the Disclosure
3.  Drawing(s) (35 U.S.C. 113) [Total Sheets 8]
4. Oath or Declaration [Total Pages ]
  - a.  Newly executed (original or copy)
  - b.  Copy from a prior application (37 C.F.R. § 1.63(d))  
(for continuation/divisional with Box 16 completed)
    - i.  DELETION OF INVENTOR(S)  
Signed statement attached deleting  
inventor(s) named in the prior application,  
see 37 C.F.R. §§ 1.63(d)(2) and 1.33(b).

\* NOTE FOR ITEMS 1 & 13: IN ORDER TO BE ENTITLED TO PAY SMALL ENTITY FEES, A SMALL ENTITY STATEMENT IS REQUIRED (37 C.F.R. § 1.27), EXCEPT IF ONE FILED IN A PRIOR APPLICATION IS RELIED UPON (37 C.F.R. § 1.28).

Assistant Commissioner for Patents  
ADDRESS TO: Box Patent Application  
Washington, DC 20231

5.  Microfiche Computer Program (Appendix)
6. Nucleotide and/or Amino Acid Sequence Submission  
(if applicable, all necessary)
  - a.  Computer Readable Copy
  - b.  Paper Copy (identical to computer copy)
  - c.  Statement verifying identity of above copies

## ACCOMPANYING APPLICATION PARTS

7.  Assignment Papers (cover sheet & document(s))
8.  37 C.F.R. § 3.73(b) Statement  Power of  
(when there is an assignee)  Attorney
9.  English Translation Document (if applicable)
10.  Information Disclosure Statement (IDS)/PTO-1449  Copies of IDS  
Citations
11.  Preliminary Amendment
12.  Return Receipt Postcard (MPEP 503)  
(Should be specifically itemized)
13.  \* Small Entity Statement(s)  Statement filed in prior application,  
(PTO/SB/09-12)  Status still proper and desired
14.  Certified Copy of Priority Document(s)  
(if foreign priority is claimed)
15.  Other: Certification Under  
37 C.F.R. 1.10

16. If a CONTINUING APPLICATION, check appropriate box, and supply the requisite information below and in a preliminary amendment:

Continuation  Divisional  Continuation-in-part (CIP) of prior application No: \_\_\_\_\_

Prior application information: Examiner Group / Art Unit: \_\_\_\_\_

For CONTINUATION or DIVISIONAL APPS only: The entire disclosure of the prior application, from which an oath or declaration is supplied under Box 4b, is considered a part of the disclosure of the accompanying continuation or divisional application and is hereby incorporated by reference. The incorporation can only be relied upon when a portion has been inadvertently omitted from the submitted application parts.

## 17. CORRESPONDENCE ADDRESS

Signature		Date	5 November 1999

Burden Hour Statement. This form is estimated to take 0.2 hours to complete. Time will vary depending upon the needs of the individual case. Any comments on the amount of time you are required to complete this form should be sent to the Chief Information Officer, Patent and Trademark Office, Washington, DC 20231. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Assistant Commissioner for Patents, Box Patent Application, Washington, DC 20231.

# **METHOD, SYSTEM AND COMPUTER PROGRAM FOR AUDITING FINANCIAL PLANS**

## Related Applications

This application claims priority from U.S. Provisional Application No. 60/107,245, filed November 5, 1998, which application is hereby incorporated by reference herein.

## Field of the Invention.

This invention relates to computer programs and related methods and systems for financial planning for individuals.

## Background of the Invention.

Financial plans are essential to the plans for retirement, saving for major expenses, such as children's education, for most individuals. If too little is saved, or the wrong investments are made, individuals will not be able to maintain their lifestyles in retirement, may not be able to send their children to desired schools, or may find themselves outliving their savings. On the other hand, if more sums than are needed are set aside for future needs, individuals may find themselves unnecessarily denying themselves and their families even minor luxuries, such as vacations and larger homes. Professional financial planners and individuals have a variety of ways of creating financial plans. The financial services industry has adopted standardized means of projecting out individual financial plans. There currently exists today no program or mechanism that allows an individual to have an accurate perception of what would have happened to their financial plan historically. In lieu of actually doing that, which is also a little bit insufficient, the financial services industry has adopted The fundamental flaw with those standard means is: 1) they use either an assumed rate of investment return over the whole period of time, and as can be proven mathematically, lacks any relation to what the values will be in the future even if those annualized returns are received, or 2) they try to statistically calculate to

come out with a forecast of statistical probability of the distribution of outcomes; by the very nature of the statistical estimation, those do not really relate to actual historical experience. In either case, the fundamental problem in any financial plan done with any of these standardized tools, either using simple annualized return as a means of estimating future values or a statistical estimation of future values, that the plans do not accurately predict the future wealth of the individual using the financial plan. For example, existing prior art tools help the individual figure out a risk tolerance, and then request the user to furnish a return expectation is or determine what the return expectations should be for the risk tolerance. These prior art tools then advise the user to expect a certain return, or a certain outcome based on a certain return, allowing for projected cash flows.

The lack of accuracy in prediction, as noted above, causes great problems for the individual. The individual may fail to meet his financial goals or forego opportunities in trying to meet those goals. A financial plan may direct an individual to save more money than she needs to, or retire later than he or she needs to. A financial plan may advise an individual that he may retire earlier than he should, or withdraw more money than he should from investments. All of this advice results from the estimation errors made through either of the current industry norms.

Financial plans are generally reviewed and revisited once every few years. The financial plan and forecasting tools are not meant to help the individual client make decisions on a daily basis about the implications of making an asset allocation decision or making purchasing decisions or retirement decisions. These decisions tend to be very long term in nature and updated fairly infrequently. Even if the tools were accurate, predictions may be made after investment, spending or retirement decisions have already been made. Their inherent nature is

such that they are not updated on a regular basis. Such plans provide little support for investors to make investment decisions.

For example, an investor feels wealthy because he has received some great market returns. His plan called for saving \$20,000 a year, and he intends to continue to do so. His current plan said he was supposed to have \$2 million at a given time, and because of great market return, he now has \$2.5 million. He then decides to make a major purchase using a portion of the additional \$500,000. He fails to rerun his financial plan. He does not know how making that purchase decision will affect his likelihood of achieving his long-term goals.

An object of the invention is to provide a method for evaluating financial plans to determine the likelihood that an investor will meet the investor's financial goals.

An advantage of the present invention is that such a method is provided. Additional objects and advantages will become evident from the detailed description of a preferred embodiment which follows.

#### Summary of the Invention.

A method for evaluating financial plans includes the steps of calculating the change in a predetermined initial value of an investment over a time interval based on changes in value over a first historical time interval to obtain a changed investment value, updating the changed investment value based on the selected amount and time to obtain a further changed investment value, calculating the change in the further changed investment value over a second time interval based on changes over a second historical time interval to obtain a further investment value, repeating the steps of calculating, updating and again calculating with respect to a third historical time interval and a fourth historical time interval, respectively, and after at least one of the

calculations, adjusting the investment value based on at least one of a contribution amount and a withdrawal amount. The method may include presenting the result of the calculations as a report to an individual. The method is preferably implemented by suitable computer software.

Investments may be categorized in more than one asset category, and distinct historical data employed in calculations for each asset category. The results of the calculation may be compared to a selected wealth goal. After each calculation relative to historical data, an adjustment of the investment value to simulate tax effects may be made.

A system for evaluating financial plans includes a computer programmed to calculate the change in a predetermined initial value of an investment over a time interval based on changes in value over a first historical time interval to obtain a changed investment value; to update the changed investment value based on the selected amount and time to obtain a further changed investment value; to calculate the change in the further changed investment value over a second time interval based on changes over a second historical time interval to obtain a further investment value, to further calculate, update and again calculate with respect to a third historical time interval and a fourth historical time interval, respectively; and, after at least one of the calculations, to adjust the investment value based on at least one of a contribution amount and a withdrawal amount.

A storage medium has stored therein instructions, wherein the instructions, when executed by a processor, cause the processor to perform the steps of:

calculating the change in a predetermined initial value of an investment over a time interval based on changes in value over a first historical time interval to obtain a changed investment value;

updating the changed investment value based on said selected amount and time to obtain a further changed investment value; and

calculating the change in the further changed investment value over a second time interval based on changes over a second historical time interval to obtain a further investment value, and

repeating said steps of calculating, updating and again calculating with respect to a third historical time interval and a fourth historical time interval, respectively; and

after at least one of the calculations, adjusting the investment value based on at least one of a contribution amount and a withdrawal amount.

#### Brief Description of the Figures.

Figures 1A, 1B and 1C are a flow chart illustrating the steps in a method according to the invention.

Figure 2 is a sample graphic representation of the result of a method of the invention.

Figure 3A and 3B is a sample chart of a result of a method of the invention.

Figure 4 is a sample chart showing another result of a method of the invention.

Figure 5 is a block diagram showing features of a system according to the invention.

#### Description of the Invention.

Referring to Figures 1A - 1C, the method of the invention is illustrated in block diagram format. Generally, the initial step is to provide to a program sufficient information about the individual, the individual's current investments, planned future contributions, and planned withdrawals, to permit the method to run. At step 102, the user is prompted to define personal information. The personal information preferably includes information important to financial

planning. The basic information includes the individual's birth date, the individual's intended retirement age, and the end age for the plan. The information may also include, if the individual has a spouse, the spouse's birth date, the spouse's intended retirement age, and the end age of the spouse for the plan.

The user may then be prompted to define one or more accounts, as shown at block 104. Preferably, these accounts are named by the user. The user is prompted to define the properties of each account as shown at block 102. The most important property of the account is the tax treatment of the account. For example, the gains on the account may be subject to current taxation. Alternatively, the gains on the account may be deferred until withdrawal. Pull-down menus may be provided to provide a selection from a variety of different types of investments, such as 401(k), 403(b), Individual Retirement Account, savings account, Education IRA, Roth IRA, investment real estate, and other investment types.

The user is prompted to provide opening balances of each account at block 108. For an effective financial plan, the opening balances preferably represent the actual present values of the accounts.

The user is prompted to furnish the planned annual contribution to each account, as shown at block 110. The program may provide for changes in planned annual contributions to accounts at different time periods in the future, or selection of the start and end age of contributions for various accounts. A default may be a level contribution starting immediately and continuing until retirement.

The user is prompted to provide planned retirement distributions, as shown at block 112. This may be a desired retirement income level. The user may further refine by providing

specific distributions from specific sources. For example, such sources might include a defined benefit retirement plan.

In a preferred embodiment, the user is then prompted to provide information on Social Security and other sources of retirement income, as shown in step 114. The user may select a desired retirement age. The program may then display annual social security benefits based on formulas or tables accessed by the program. Such formulas or tables have been constructed from publicly-available Social Security benefit information.

The user is prompted to enter additional withdrawal information at block 116. For example, a form may be provided to input the age of each child what levels of education will be paid by the individual, and the expected cost per year. The amount and time of the expected withdrawals from investments may then readily be calculated. Other anticipated large expenses may optionally be included.

The user is then prompted to enter allocations of assets by asset categories, as shown at block 120. The asset categories are preferably large categories, such as large capitalization stocks, small capitalization stocks and foreign investments, bonds, and Treasury bills and cash. The selection of particular categories may be altered. The desired categories should be those as to which considerable historical data is available. It is preferred to assume essentially a passive investment, rather than looking at historical returns of particular managed investments. Depending on the features desired, asset allocations may be selected separately for both currently taxable and tax deferred investments. A further feature that could be added would be changes in asset allocations at different times in the future. The user may also be prompted to input expected, optimistic, and pessimistic returns on investments.

The user may also be prompted to enter a number for investment expenses. If investment expenses are given a positive percentage, this would indicate investments that underperform the market historically. If investment expenses are given a positive percentage, this would indicate investments that outperform the market historically.

The user is then prompted to enter tax information, as shown at block 122. This information preferably includes Federal income tax filing status, State of residence, and any local tax rates. The program may access tables to look up applicable Federal ordinary and capital gains income tax rates and state tax rates. Local tax rates may also optionally be entered. Tax rates may be entered from a look-up table separately for pre-retirement and retirement rates.

It will be understood that the order that the foregoing information is furnished may be changed without affecting the method. The information preferably includes as much information as possible relevant to the individual's projected cash flow into and out of investments and other retirement income.

The option of selecting an assumed inflation rate may be provided. Different inflation rates may be used with respect to different investment categories. The option may be provided of furnishing results in inflation-adjusted dollars or actual dollars.

When all the desired information has been entered, the user is prompted to run the calculation. The program has stored a series of changes in values for each separate category of assets for a selected number of time periods. The time periods may be, for example, years, months, or shorter or longer periods as desired. The performance of the plan, will then be determined assuming a large number of different starting points. Based on the input asset allocations and the current holdings values, starting values for each asset allocation and each tax

status are calculated, as shown by block 124. The program selects a time period, as shown by block 125. The performance for the first selected time period is then calculated based on the historical data, separately for each asset allocation and tax status, as shown by block 126. The performance may be adjusted either before the calculation or after the calculation by the investment assumptions. For currently-taxable investments, any gain is adjusted by deducting appropriate amounts based on assumed tax rates, as shown by block 128. The gain is added to the value in each category, as shown by block 130. The contribution at the end of the time period is then added to each category, based on asset allocations and previously defined contribution amounts. Alternatively, if the year of the plan calls for a withdrawal, for retirement needs, education or otherwise, the appropriate adjustment is made to the values. This is shown by block 132. This value is stored as an ending value. The method then checks to see if the final year for the plan has been reached, as shown by decision block 136. If not, the method returns to block 125, a new time period is selected, and the calculations are repeated, using historical data from the next year in the applicable table, and the contribution, withdrawal, distribution and tax information from the next year in the plan. The method repeats until the last year of the plan is reached. When the final year of the plan is reached, the method checks to see if the total number of starting points is the final number of starting points, as shown by decision block 138. If not, then the entire method repeats, using the same opening balances as allocated, commencing from a different starting point. This is repeated until the desired number has been completed. A possible minimum number is 32 different starting points. The calculation need not be performed for consecutive years. For example, the number of years of the plan may exceed the number of years of historical data. In one embodiment, each test is run from the start point consecutively

until one-half of the time period of the plan is reached, and then the calculation returns to the start point. Other methods may be used if the number of plan years exceeds the historical data.

To determine the appropriate amount to be withdrawn, Social Security and other sources may be deducted from the desired annual retirement income amount.

For purposes of comparison to a standard calculation, the program that implements the method can also calculate the returns based on a flat annual rate of return, without reference to historical data.

The method then provides the results in a display for the user. Preferably, only certain results are selected for display. For example, the tests may be ranked by ending value. A middle ending value, ranked at 50% probability, may be selected. An ending value representing a result better than all but one percent of the results may be selected and labeled as having a 99% probability of success. The results may be displayed in tables or graphically in a variety of formats. For example, the results may be displayed in a graph showing age against value of investments. Sample results for fictional assumptions are shown graphically at Figure 2. Line 202 represents a standard result based on a steady annual increase in value. Line 204 represents values based on a result worse than 99% of the starting points. Line 206 represents a result that is at the midpoint of the analyses that were run.

As shown in Figure 3A and 3B, the results may also be displayed as a table. The table may show the plan year, from the date the plan is run, as shown at 302, the age of the individual at the time of the plan, as shown at 304, and the ending value, as shown at 306. Additional information, such as the cash flow into or out of investments, the yield on investments in the

year, the appreciation or depreciation in value of investments, and the taxes, may also be shown for each plan year.

The report may also include a detailed analysis listing the ending value and market periods for each test that was run. A sample is shown as Figure 4. The tests are ranked in order from highest ending value to lowest. Column 402 displays probability of obtaining at least the ending value listed. Column 404 displays the ending value of each test. Column 406 displays ranking each test from most assets to least assets.

Other displays may include a display of cash flows into and out of investments, showing contributions to investments, withdrawals, and retirement distributions, on a year-by-year basis.

The program and system may also provide the user, together with the results of the plan, the opportunity to adjust various variables to ascertain the change in historical results. For example, an input may be provided to permit the user to change asset allocations, retirement age, contribution amounts, distribution amounts, and amounts of other withdrawals.

The program may be made accessible to users at client computers connected on the World Wide Web to a server running the program. Web-based forms may prompt the user to provide required and optional information. The results of the analysis may be displayed on the page. The results may also be presented as a report in a convenient format, such as portable document format (pdf) for downloading to the client computer, or may be e-mailed from the server to an address identified by the user at the client computer. This format is advantageous in that the tables containing historical data can readily be supplemented, and tables containing tax rate information can readily be updated. Also, a financial planner and a client can share a report on a web server with suitable security.

Figure 5 illustrates a system according to the invention. Processor 505 is running in a server computer. Processor 505 is connected to client computer system 510 via Internet 515. As noted, the world wide web may be used for interchange of data. Processor 505 accesses program files 520 for instructions. Program files 520 are stored on a suitable storage medium, such as a hard drive, CD-ROM or other storage medium. Processor 505 accesses general files 525, which contain, non-exclusively, as shown by block 530, historical performance data, by time period, for different categories of investments, tax data, and Social Security data. Processor 505 may also access client files 535, which contain, as shown by block 540, non-exclusively, investment values, asset allocations, contributions, age and retirement age. Processor 505 causes the data in block 540 to be updated and changed based on data received from client system 510 in accordance with instructions contained in program files 520.

The use of the method, system and program of the invention is not limited to running on a web server. Copies of the program may be distributed on physical media or by electronic transmission.

In testing this method, the inventor has observed tremendous differences between the present invention and prior art tools, depending on the individual's pattern of contributions and withdrawals and the resulting periodic balances of their investments.

The result may be expressed as the percentage of outcomes for which the desired financial goal is actually achieved. That financial goal can be, for example, a certain amount of wealth by a certain date, or a desired stream of withdrawals. The probability of success may be expressed a percentage. The inventor believes that the analysis of a financial plan using the

method of the invention will, notwithstanding the annualized rate of return, advise the individual investor as to the likelihood of achieving his objectives.

The method of the invention gives the investor the distribution the results of any financial plan based on historical market outcomes. Probabilities of obtaining certain outcomes can be derived from the distribution. Some financial plans, subjected to this analysis, will show that the investor would have run out of money before the plan indicated that. This permits the investor to know, for example, that the investor has a one-in-ten chance of failing to meet his objective.

Based on this information, an investor may choose to adjust the financial plan to provide for less risk.

Unlike prior art analyses, the results of the method of the invention are unique to the asset allocation, planned contributions and withdrawals, beginning wealth, and risk tolerances of each user. For example, for one investor, lowering the small capital stock/foreign allocation may increase the likelihood of running out of money. For another investor, increasing the small capital stock/foreign allocation may increase the likelihood of running out of money.

The software may be enhanced to include a mechanism for the investor to prioritize their financial outcomes. For example, an investor may have a goal of having a certain probability of having \$10 million at age 85. The investor may prefer to retire at 65, but would be willing to retire as late as 70. The same investor may be able to save up to \$40,000 per year, but may strongly prefer not to save more than \$20,000 per year. By weighting the variables, the investor can then have the program run a series of scenarios. This will then provide the investor with a number of different options that meet the criteria.

The method of the invention may be used dynamically by investors for guidance in making investment and purchase decisions. For example, an investor may find that, by foregoing a purchase, he may retire earlier, or increase his likelihood of achieving his savings goal at retirement, by not making the contemplated purchase. An investor contemplating an investment may find that, depending on the category of investment, she may either increase or decrease her likelihood of achieving her financial goals.

The planning software of the invention, including the historical data on which the calculations are based, can be made available to the investor to update based on the actual current data on the value of investments. Data could be transferred automatically from financial services providers to client files on a server so that the updates could be accomplished without requiring the data to be input by the investor.

The processor may be an Intel Pentium or similar microprocessor. The method can be implemented in custom software, or in spreadsheet software such as Excel. The computer program with commands that cause a computer to execute the method can be stored on any storage medium that now exists or may be developed in the future, including fixed disk drive, floppy discs, and CD-ROM. The computer program may also be transmitted as a digital signal over telephone lines, other transmission lines, or via radio waves. The signal may be transmitted in packets over a packet-switched network, such as the Internet.

The computer program in accordance with the invention may be stored and distributed in any suitable storage medium, such as fixed disk, portable diskettes, and CD-ROM or other read-only memories. Also, methods described as being carried out in software running on general-purpose computer hardware may be implemented in hardware.

It will be understood that various changes in the details, materials and arrangements of the methods and systems which have been described and illustrated above in order to explain the nature of this invention may be made by those skilled in the art without departing from the principle and spirit of the invention.

What is claimed is:

1. A method for evaluating financial plans, comprising the steps of:
  - calculating the change in a predetermined initial value of an investment over a time interval based on changes in value over a first historical time interval to obtain a changed investment value;
  - updating the changed investment value based on said selected amount and time to obtain a further changed investment value; and
  - calculating the change in the further changed investment value over a second time interval based on changes over a second historical time interval to obtain a further investment value, and
  - repeating said steps of calculating, updating and again calculating with respect to a third historical time interval and a fourth historical time interval, respectively; and
  - after at least one of the calculations, adjusting the investment value based on at least one of a contribution amount and a withdrawal amount.
2. The method of claim 1, further comprising the step of presenting the result of said steps to an individual.
3. The method of claim 1, wherein said investments are categorized in more than one asset category, and distinct historical data is employed in calculations for each of said asset categories.
4. The method of claim 1, wherein the results of said calculation are compared to a selected financial goal.

5. The method of claim 1, wherein, after each calculation relative to historical data, an adjustment of the investment value to simulate tax effects is made.

6. The method of claim 1, further comprising the step of prompting a user to enter the initial investment value, and allocations to asset categories.

7. A system for evaluating financial plans, comprising:

means for calculating the change in a predetermined initial value of an investment over a time interval based on changes in value over a first historical time interval to obtain a changed investment value;

means for updating the changed investment value based on said selected amount and time to obtain a further changed investment value;

means for calculating the change in the further changed investment value over a second time interval based on changes over a second historical time interval to obtain a further investment value, and

means for further calculating, updating and again calculating with respect to a third historical time interval and a fourth historical time interval, respectively; and

means for after at least one of the calculations, adjusting the investment value based on at least one of a contribution amount and a withdrawal amount.

8. The system of claim 7, further comprising means for presenting the result of said steps to an individual.

9. The system of claim 7, further comprising means for categorizing said investments in more than one asset category, and for employing distinct historical data in calculations for each of said asset categories.

10. The system of claim 7, further comprising means for comparing the results of said calculation to a selected financial goal.

11. The system of claim 7, further comprising means for, after each calculation relative to historical data, adjusting the investment value to simulate tax effects.

12. The system of claim 7, further comprising means for prompting a user to enter the initial investment value, and allocations to asset categories.

13. A storage medium having stored therein a plurality of instructions, wherein the plurality of instructions, when executed by a processor, cause the processor to perform the steps of:

calculating the change in a predetermined initial value of an investment over a time interval based on changes in value over a first historical time interval to obtain a changed investment value;

updating the changed investment value based on said selected amount and time to obtain a further changed investment value; and

calculating the change in the further changed investment value over a second time interval based on changes over a second historical time interval to obtain a further investment value, and

repeating said steps of calculating, updating and again calculating with respect to a third historical time interval and a fourth historical time interval, respectively; and

after at least one of the calculations, adjusting the investment value based on at least one of a contribution amount and a withdrawal amount.

14. The storage medium of claim 13, wherein the plurality of instructions, when executed by a processor, cause the processor to perform the further step of presenting the result of said steps to an individual.

15. The storage medium of claim 13, wherein the plurality of instructions, when executed by a processor, cause the processor to perform the further step of, for investments categorized in more than one asset category, employing distinct historical data is employed in calculations for each of said asset categories.

16. The storage medium of claim 13, wherein the plurality of instructions, when executed by a processor, cause the processor to perform the further step of comparing the results of said calculation to a selected financial goal.

17. The storage medium of claim 13, wherein the plurality of instructions, when executed by a processor, cause the processor to perform the further step of, after each calculation relative to historical data, adjusting the investment value to simulate tax effects.

18. The storage medium of claim 13, wherein the plurality of instructions, when executed by a processor, cause the processor to perform the further step of prompting a user to enter the intial investment value, and allocations to asset categories.

## ABSTRACT OF THE DISCLOSURE

A method for evaluating financial plans includes the steps of calculating the change in a predetermined initial value of an investment over a time interval based on changes in value over a first historical time interval to obtain a changed investment value, updating the changed investment value based on the selected amount and time to obtain a further changed investment value, calculating the change in the further changed investment value over a second time interval based on changes over a second historical time interval to obtain a further investment value, repeating the steps of calculating, updating and again calculating with respect to a third historical time interval and a fourth historical time interval, respectively, and after at least one of the calculations, adjusting the investment value based on at least one of a contribution amount and a withdrawal amount. The method may be repeated numerous times using various start dates for the historical data to obtain a range of possible results. The method may include presenting the result of the calculations as a report to an individual. The method is preferably implemented by suitable computer software. Investments may be categorized in more than one asset category, and distinct historical data employed in calculations for each asset category. The results of the calculation may be compared to a selected wealth goal. After each calculation relative to historical data, an adjustment of the investment value to simulate tax effects may be made.
